

Ideogram PM take-home: Brand-consistent image generation

Build a web app that generates on-brand campaign images for a small business.

▼ User flow

1. User uploads a logo and up to 5 example images that represent their brand.
2. User describes the image they want (e.g., "product shot of a new summer drink," "lifestyle photo for a back-to-school post").
3. System generates 2 on-brand images using nano banana 2.
4. User can regenerate.

▼ What we mean by "working"

This does not have to work perfectly. Off-the-shelf models will struggle with parts of this problem, and that is the point. What we want is a prototype that is good enough to reveal where the hard problems are: where does the model respect the brand, where does it fail, and what would you build next to close the gap.

▼ Constraints

- Use Gemini Flash Image (nano banana 2) for generation. We want to see what off-the-shelf can do and where it breaks.
- Time budget: 4 hours.
- We'll provide you with Claude Code or Codex access, plus an API key with a spending cap. Use whichever you prefer.
- Deploy it somewhere clickable so we can try it too. Please send us the link plus a short Loom (maximum of 5 minutes) walking us through your decisions.

▼ What we're evaluating

- **Scoping:** what you built vs cut, and why

- **Model judgment:** how you got the model to respect the reference images and logo, where it failed, and what you learned
- **UX taste:** does the flow feel obvious and product-like
- **Shipping:** does it actually work end-to-end

▼ **More context**

- We aren't evaluating app polish, auth, payments, production concerns, or perfect output quality.
- In your Loom, please tell us what you used the AI tools for and where you overrode them. We are especially interested in what you would build next if you had another week.

▼ **Why we're asking you to build something**

The PM role is changing. AI coding tools have collapsed the cost of prototyping, so the bottleneck is primarily "do we know what's worth building, and can we feel it working in our hands fast enough to learn." Writing a PRD to describe a product you could have just built is starting to look unnecessary.

We think the most productive PMs in this shift are builders. Not full-time engineers, but people who can prototype their own ideas, run their own experiments against real models, and bring working artifacts into product discussions instead of documents. This matters even more in AI products, where the behavior of the underlying model is the product, and you cannot reason about it abstractly. You have to touch it.

That is why this exercise asks you to ship something instead of writing a spec. We are not looking for polish. We are looking for the instincts of someone who can operate as a builder-PM on a small team where shipping and learning fast is the whole game.
